PROMPTS GIVEN:

1.Suggest an appropriate JavaScript data structure for storing menu items with name, category, price, image path, and quantity.
2.Explain how JavaScript's filter() method can be used to display only menu items belonging to the selected category.
3.Explain how to dynamically generate menu cards from a JavaScript array using DOM manipulation instead of manually writing HTML.
4.Explain how JavaScript's filter() method can be used to display only menu items belonging to the selected category.
5.Explain how event listeners work for dynamically created Add to Cart buttons.
6.Explain different approaches for implementing a shopping cart in JavaScript and Explain why cart indices and original menu indices differ and suggest the correct approach for implementing Remove functionality.
compare storing duplicate objects versus maintaining a quantity property..
7.While filtering the menu, Add to Cart always adds Pizza regardless of the selected item. Analyze the cause and suggest a correction without changing the overall project structure.
8.Suggest an efficient method to recalculate the cart total whenever items are added or removed.
10.Review the JavaScript implementation and identify logical errors, edge cases, and opportunities to improve readability without rewriting the entire project.
